

Values and their types

Every value has a type. You inspect it with `type()`, and `repr()` shows a value the way you would write it in code:

- `42` — `int`
- `3.14` — `float`
- `"hello"` — `str`
- `true` — `bool`
- `12pt` — `length`
- `50%` — `ratio`
- `[bold]` — `content`
- `(1, 2, 3)` — `array`
- `{name: "Ada"}` — `dictionary`

Two special values stand apart: `None`, which is deliberately nothing, and `auto`, which means “let Typst decide”. Each is the sole member of its own type.
